

ABSTRACT of the DISCLOSURE.

The modellable tile has an upper surface and a bottom surface and comprises a thin and flexible support element associated to the bottom surface, and at least one recess which involves a whole width of the tile but not the thin and flexible support element. The recess separates the tile into at least two parts which are totally separated one from another, which parts exhibit upper edges which are located side-by-side and which are destined to be brought into reciprocal contact in order to give the tile a predetermined non-flat conformation.
